Investigation of the Main Factors in the Recrystallization of
Technical Iron in Rapid Electric Heating

and size of grains at times up to 5 seconds at 630 °C is shown in Fig.5. Fig.6 shows the linear fall with rising reciprocal of absolute temperature of the rates of nucleation (N) and growth (G) of recrystallization grains (curves 1 and 2 after deformation and after tempering, respectively). Preliminary tempering leads to a reduction in both N and G for annealing temperatures below 600 °C but has no effect at higher temperatures. The authors discuss the kinetics of the process in terms of N and G and also the activation energies and the coefficient in the exponential time - reciprocal absolute temperature relation (values are tabulated). There are 6 figures, 1 table and 5 Soviet references.

On the Self-Braking of Reverse-Blade Hydroturbines

The author examines the emergency braking of hydroturbines accomplished by adjusting the blades of the water wheel to a position for which the turning moment, of the stopped wheel is equal to zero. In theory there are four possible positions for the blades. Experiments have shown that two of them do not give stable braking. The author determines the other two positions theroretically using the method of D.A. Voytashevskiy. (RZhMekh, No. 6, 1955) Tr. Vses. n.-i. in-ta Gidromashinostri, No. 18, 1954, 32-51.

AUTHORS: Rolinskiy, V. Yu. and Ivanov, V. I.
TITLE: Method of averaging Reynolds' criterion with inhomogeneous distribution of velocities in space and time
PERIODICAL: Referativnyy zhurnal, Mekhanika, no. 7, 1962, 78, abstract 7B532 (Tr. Nikolayevskogo korablestroit. in-ta, 1961, no. 22, 71-75)

TEXT: The authors propose a method of averaging to obtain an average Reynolds' number in conditions of harmonic oscillating motion of the medium, beginning with the condition that the average value to be obtained must be equal to the value of Reynolds' number for stationary flow past bodies securing the same heat flow as in oscillating motion. Averaging over $1/4$ of a period one obtains the following expressions: $R_{eff} = 0.562R_A$, R_{eff} being the corresponding average value and R_A the amplitude of the actual Reynolds' number.

- In the case of the velocity field being inhomogeneous in space the

Orig Pub : Zh. tekhn. fiziki, 1956, 26, No 4, 874-877

Abstract : To eliminate packing gaskets, which are the weak point in super-high pressure setups, a compression chamber was developed with a conical piston. The conical piston is pressed into a carefully ground socket and normal pressure is produced on the periphery of the cone. The cone angle is chosen to make this pressure always greater than the pressure produced by the piston in the liquid, thereby insuring hermeticity. The construction is described and the design calculations (employing the theory of elasticity) are given for the first version of such a setup. A pressure up to 14,000 kg/cm² was obtained, the pressures being measured with a manganin manometer.

PURPOSE: This collection of articles is intended for physicists, sanitation and public health doctors, chemists and other specialists working in radioactive dosimetry.

CONTENTS: This work discusses the following subjects: (1) principles of organizing sanitation and dosimetric control in institutions where work is carried on with radioactive substances; (2) radio-chemical and chemical methods for determining certain radioactive substances in samples of air, water, soil and foodstuffs; (3) physical methods of measuring contamination of the air by radioactive gases and aerosols, clothes and leather coverings; (4) methods of contamination of soil, tissues of α - and gamma-radiation, and methods of measuring individual dosimetric monitoring; (5) Absolute and relative methods of measuring the activity of solid and liquid radioactive sources. There are four appendices dealing with methods of calculating the total dosage from various sources of ionizing radiation, units of activity, and doses from natural (background) radioactivity in the calcium of foodstuffs. Sanitary regulations observed during transportation, storage, and handling of radioactive substances are discussed, as well as the permissible level of ionizing radiation. The editors thank Yu.Y. Shvintsev and B.P. Shvintsev. References appear at the end of each chapter.

TITLE:

The Spatial Distribution of Ions in a Liquid
(Prostranstvennoye raspredeleniye ionov v zhidkosti)

PERIODICAL:

Atomnaya energiya, 1959, Vol 7, Nr 1, pp 73-74 (USSR)

ABSTRACT:

Several papers (Refs 1-3) already investigated the influence exercised by the ionizing particles and by the nature of the irradiated medium upon the ion distribution in it. Essentially, ion distribution is determined by the nature of the traces of the ionizing particles, which is especially marked in the case of liquids (greatest ion density along the traces). After irradiation of longer duration, it may be assumed that part of the ions is distributed uniformly over the entire irradiated volume, whereas the other part is concentrated in so-called cells. These cells are of spherical or cylindrical shape (between a sphere and a cylinder). In the present "Letter to the Editor" the author investigates the concentrations of these two parts and also the influence exercised by irradiation conditions upon the concentrations. For this purpose he proceeds from the assumption that, at the moment of their production, all ions are concentrated in homogeneous cells of the volume V_0 .

Card 1/2

The Spatial Distribution of Ions in a Liquid

SOV/89-7-1-15/26

By recombination and diffusion, the concentration is supposed to decrease to such an extent that, after the time τ , it is equal to that of the background. In the following, explicit formulas, according to which the final ion concentration in cylindrical and spherical cells may be calculated, are deduced. The formulas are more accurate than those obtained by Magi (Ref 3). It was found that the relative concentration of the background increases with an increase of the primary cell volume and with radiation intensity; this may explain some of the rules of liquid ionization chambers. There are 3 references, 1 of which is Soviet.

TITLE: The Effect of Polarity in Liquid Ionization Chambers

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Fizika,
1960, Nr 1, pp 115-118 (USSR)

ABSTRACT: It is found that the magnitude of the ionization current in liquid ionization chambers depends on the sign of the voltage applied. The effect is due to the fact that the true potential difference applied to the liquid is not equal to the external potential difference but differs from it by a quantity which, in general, depends both on the external potential difference and the intensity of the radiation. The nature of the additional potential difference depends on experimental conditions and is not always clear. A partial manifestation of the presence of an additional potential difference is the appearance of an ionization current when the chamber is irradiated with X-rays with the external potential difference reduced to zero. This may be due to: 1) contact potential difference, 2) unequal ejection of electrons

Card 1/3

69446
S/139/60/000/01/020/041
E201/E491

The Effect of Polarity in Liquid Ionization Chambers

from the electrodes of the chamber and 3) unequal conditions for positive and negative ions due to the absorption of the primary radiation by the liquid. In order to have a correct interpretation of ionization measurements, it is necessary to know the above additional voltage as a function of the external voltage and the intensity of the incident radiation. The present author has investigated this problem, using plane parallel ionization chambers filled with non-polar organic liquids. It was found that the current measured with the external potential difference reduced to zero is strictly proportional to the square root of the intensity of the incident X-rays (Fig 1). It follows that the corresponding residual potential difference is independent of this intensity. Experiments show that the additional potential difference which is equal to the difference between the external and the true potential differences remained constant throughout the experiment.

Card 2/3

It was found equal to that in the absence of the external

69446

The Effect of Polarity in Liquid Ionization Chambers

potential difference. In order to exclude the effect of the polarity on the volt-ampere curve it is necessary to take one half of the algebraic difference between currents obtained with opposite signs to the external applied voltage. The above results applied so long as the saturation region is not reached. There are 3 figures and 2 Soviet references.

TITLE: The Effect of the Structure of the Ionization on the
Volt-Ampere Characteristics of a Liquid Ionization Chamber

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Fizika,
1960, Nr 1, pp 119-123 (USSR)

ABSTRACT: A feature of the structure of the ionization in
condensed media is the fact that the ions produced by
each ionizing particle may be localized in isolated
regions of space within which recombination takes place.
In the case of heavily ionizing particles such as
 α -particles, protons and slow electrons, these localized
regions of ionization are roughly cylindrical "columns"
whose axis lies along the particle track. Such "columns"
have been discussed in detail by Jaffe (Ref 1). As soon
as they are formed, the "columns" begin to expand owing
to diffusion. If the intensity of the radiation
producing the ionization is sufficiently low, most of the
ions in a given "column" will recombine before the overlap
between the different "columns" takes place. In that case

Card 1/5

69447

S/139/60/000/01/021/041
E032/E414

The Effect of the Structure of the Ionization on the Volt-Ampere
Characteristics of a Liquid Ionization Chamber

there is no recombination between ions belonging to different "columns" and the ionization current is due mainly to those ions which have been extracted by the electric field from the "columns" and is characteristic of them. The dependence of the current on the electric field is given by Eq (1) (Jaffe's formula) where α is the recombination coefficient, N_0 is the number of ion pairs per unit length of a "column" at the time of its foundation, D is the diffusion coefficient, i is the ionization current corresponding to a field E , and i_0 is the saturation current. The function $f(z)$ is a complicated function in which z is proportional to the square of the electric field. Well away from the saturation region, and for sufficiently small z , the function $f(z)$ is given by Eq (2). The higher the intensity of the radiation, the greater the number of ions which are distributed uniformly over the irradiated region, and one may consider that new "columns" are formed on a background of a uniform ion concentration. ✓

Card 2/5

69447

S/139/60/000/01/021/041
E032/E414

The Effect of the Structure of the Ionization on the Volt-Ampere Characteristics of a Liquid Ionization Chamber

Eq (1) cannot be used if the concentration of the uniformly distributed ions cannot be neglected in comparison with the ion concentration in the "columns". In the limiting case of a uniform ionization, when the usual volume recombination takes place, the dependence of the ionization current on the potential difference across the chamber is described by Eq (3) (Ref 2), where U is the potential difference applied to the chamber and R_0 is the resistance of the chamber when $U = 0$. The quantity C is a constant and depends on the properties of the ionized medium. It is shown that if the theory leading to Eq (3) is correct, then the graph of the function $f(U) = 2R/(R_0 - 1)^2$ should be a straight line, while if Jaffe's theory applies, the equation $i^{-1} = \varphi(\ln U)$ should be a straight line. The functions $f(U)$ and $\varphi(\ln U)$ are defined by the right-hand sides of Eq (1a) and (3a), where $R = U/i$. Experiments indicate that neither of these relations will

S/139/60/000/01/021/041
E032/E414

The Effect of the Structure of the Ionization on the Volt-Ampere Characteristics of a Liquid Ionization Chamber

describe the volt-ampere characteristic of the liquid ionization chamber away from the saturation region. It has been established by the present author that experimental data can be described by the expression

$$i = U / (R_0 + U/\gamma i_0) \quad (4)$$

where γ is a constant for a given chamber. The experimental data leading to this result are plotted in Fig 3. These data may be extrapolated to zero potential difference across the chamber so that R_0 may be determined. All the measurements were carried out in a liquid ionization chamber having a plane parallel geometry, the distance between the electrodes being 4.6 mm. It was found that $R_0 \sim i_0^{-1/2}$. It follows from these results that under the above conditions the main contribution to the ionization current is due to the uniform background distribution. The paper is

The Effect of the Structure of the Ionization on the Volt-Ampere
Characteristics of a Liquid Ionization Chamber

concluded with a discussion of how the "uniform background" is formed. It is concluded that the fraction of ion taking part in this uniform background is given by Eq (7) where q_1 is the rate of formation of the background ions and q is the rate of formation of ions in general. Eq (7) shows that the fraction of ions taking part in producing the uniform background decreases with increasing potential difference across the chamber. The equilibrium concentration of the background ions is given by Eq (8) in which h is the distance between the electrodes and K_1 and K_2 are the mobilities of the positive and negative ions. There are 3 figures and 3 references, 1 of which is Soviet, 1 German and 1 English.

TITLE:

Investigation of a Used Fuel Element of the First Nuclear
Power Station

PHYSICAL: Atomic energy, 1960, Vol. 8, No. 5, pp. 446 - 447

TEXT: In the present paper the authors give a report on investigations of the isotopic composition, the burnup and the state of the used fuel elements of the Pervaya Atomnaya Elektrostaniya (First Nuclear Power Station) of the Soviet Union. The fuel elements investigated had been in operation for 150 days. Carrying out of the remote investigations is briefly described. A thin oxide film was found on the outer shell of the fuel element. The outer diameter of the fuel element was found to be 14.11 ± 0.02 to 14.20 ± 0.02 mm was found. An investigation

of the inner shell showed that it had a brown deposit (about 10 thick) which was identified as an impregnation (and not as a corrosion product of steel). The burnup was determined according to the G_{235} -activity, which was separated chromatographically by the sample from the element. This isotope was especially well suited because of its long half-life. Fig. 1 shows the curve of burnup along the element (from bottom to top). The burnup was found to be 15.1% at the bottom and 16.1% at the top. The uranium content in these samples was 9.3%, which corresponds to a burnup of 16.1%. Fig. 2 shows the distribution of the entire α , β , and γ -activity along the element (from bottom to top). The transuranium-isotope content was determined according to the alpha spectra and the number of spontaneous fissions. Fig. 3 shows the distribution of the isotopes Pu^{240} , Pu^{239} , and Am^{241} along the fuel element. The Pu^{239} content is given in Table (2.3-10⁻⁴ to 1.20, 0.102, 1.27-10⁻², 1.86-10⁻³) and is compared with several theoretical

TITLE: A dosimeter of mixed gamma-neutron radiation

PERIODICAL: Referativnyy zhurnal, Fizika, no. 2, 1963, 72, abstract 2A478
("Sb. rabot po nektorym vopr. dozimetrii i radiometrii ionizir. izluchenyi", no. 2, M., Gosatomizdat, 1961, 121 - 124)

TEXT: The possibilities of developing a device are discussed which would permit to measure the neutron and γ -ray doses in mixed flow simultaneously with one pickup, with allowance being made for the relative biological effectiveness of these kinds of radiation. A way is suggested which involves the application of a proportional counter as the pickup of such a dosimeter. The idea of the method is based on the fact that pulses produced in the proportional counter due to protons have, on an average, a greater amplitude than pulses due to electrons. The block diagram of a dosimeter is given in which this principle is applied, and the functions of the individual units of the dosimeter are described in detail. An examination of the applicability of the method suggested was performed

Card 1/2

A dosimeter of mixed gamma-neutron radiation

S/058/63/000/002/008/070

on a dosimeter model with the proportional counter filled with BF_3 . The usual counter CHM-5 (SNM-5) surrounded by a paraffin layer for slowing-down neutrons from a Po-Be source was used. It was established that the pulses arising in the counter during the capture of thermal neutrons are markedly greater than the pulses arising due to the action of γ -rays. The results of the examination performed with Po-Be neutron sources and radium as the γ -source showed the full applicability of the suggested method for dosimetric purposes. Rough estimates of the accuracy of the method were made.

TITLE: Study of a used fuel rod from the First Nuclear Power Station

PERIODICAL: Atomnaya energiya, v. 11, no. 2, 1961, 122-125

TEXT: This is the second part of a paper, the first having been published in "Atomnaya energiya" v. 8, no. 5, 1960, 446. Results of studies of used fuel rods from the Pervaya atomnaya elektrostantsiya (First Nuclear Power Station) are presented. The element jackets displayed no changes apart from some oxide stains. A comparison between the diameters of a new fuel rod with one after 104 and another after 445 effective burning hours showed that while the diameter had not increased at the upper and lower rod ends, it had grown by less than 0.2 mm in the middle. In order to measure the total α -, β -, and γ -activity, the used fuel rod was divided lengthwise into 10 sections, and each of these parts was dissolved in nitric acid. The α -activity was determined by a Da-49 (Da-49) standard device and an ionization chamber, the

β -activity by a 4 π -counter, the γ -activity by an ionization chamber as compared to a radium standard. The activity of the inner and outer tubes bounding the fuel element was also measured; these tubes were made of stainless steel. In the middle, the activity of the outer tube was 30% higher than that of the inner tube. This effect can be explained by the change of the neutron spectrum along the diameter of the fuel element. The burn-up in the used fuel elements was determined on the strength of the absolute activity of cesium which was separated by an ion exchanger. The results of a radiometric determination of the burn-up were compared with mass-spectrometric results, and agreement was found to be good. The mean burn-up of the entire element was found to be equal to 53%. Finally, the isotopic composition of transuranic elements was also determined in the used-up fuel. The first part of the present paper has supplied the results of a radiometric determination of the isotopic composition in case of a 12.5% burn-up of the element. The results of a mass-spectrometric analysis are now given. The substance under investigation was to the emitter (tungsten foil, 40 μ) in the form of an aqueous nitrate solution. A thermal ion source served for the purpose. Results are presented in Fig. 5. They were used to calculate the mean values of isotopic composition. The

the Second Geneva Conference (1958). Inside the core the neutrons have energies of more than 100 kev which they lose almost completely in passage through reflector and shield. In the outer layers of the shield, their mean energy does not exceed some tens of ev. In the kev range ($E_n > 50$ kev)

spectra were measured for the most important beams and channels. For the other cases, they were determined from threshold reactions. The soft part of the spectrum within the reflector was determined from the spatial distribution of neutrons with $E_n \leq 5$ ev, recorded with gold resonance indicators. The total neutron flux was determined only at the points where

the Pu^{239} fission cross section was constant. Direct neutron spectrum measurements were carried out in a vertical (OK-70) and a horizontal (B-3)

channel using ($\text{He}^3 + \text{Ar}$)-filled ionization chamber in the first case and the neutron transmission method with n-hexane in the second. The neutron spectrum of the horizontal channel was also determined by photoemulsions.

From the rates of indicator and fission reactions $\text{Au}^{197}(n,\gamma)$, $\text{U}^{235}(n,f)$, $\text{Pu}^{239}(n,f)$, $\text{Th}^{232}(n,f)$, $\text{Na}^{23}(n,f)$, $\text{Cu}^{63}(n,\gamma)$, and $\text{Al}^{27}(n,\alpha)$ the abrupt

drop in neutron energy in the Ni reflector was determined, and the activity caused by resonance neutrons ($E_n = 4.9$ ev). The fast neutron flux ($E_n > 1.4$ Mev) in the core center was found to be $(2.4 \pm 0.2) \cdot 10^{14}$, and total flux was $(8.2 \pm 0.3) \cdot 10^{14}$. Experimental results were verified by energy-group calculations (18 groups). Good agreement between theory and experiment was also found for the channel spectra. The authors thank D. S. Pinkhasik, N. N. Aristarkhov, and the reactor personnel for assistance. There are 10 figures, 2 tables, and 2 Soviet references.

TITLE: Use of resonance indicators for investigating neutron spectra
in fast reactors

PERIODICAL: Atomnaya energiya, v. 11, no. 6, 1961, 522 - 527

TEXT: The authors studied the possibilities of using resonance indicators
for investigating the low-energy part of neutron spectra in the reflectors
of fast reactors. The resonance blocking method is discussed in detail.
In this case, the indicator foil is covered on both sides by thin
shielding layers, except in the vicinity of resonance at $E = E_0$.

Resonance neutron flux can be calculated by measuring the activity difference

$$\Delta A = \varphi(E_0) \frac{\pi}{2} \Gamma_V \Sigma_{0,a} +$$

$$+ 2t \int \Sigma_a(E) \Sigma_c(E) \left\{ 1 - \frac{1}{2} \times \right.$$

$$\times E t [-\Sigma_c(E)t] \left. \right\} \varphi(E) dE. \quad (1)$$

Card 1/1 C/

Use of resonance indicators...

21109
S/089/61/011/006/005/014
U102/U138

of the resonance parameters, for determining blocking factor η are known. $\varphi(E)$ is neutron flux, Γ_γ the radiation width, $\Sigma_{0,a}$ activation cross section in the resonance maximum, Σ_a and Σ_c activation cross section of the indicator isotope and total absorption cross section of the indicator respectively. η is calculated on the basis of the Gurevich-Pomeranchuk theory of resonance absorption (e. g., G. I. Marchuk, Chislennyye metody rascheta yadernykh reaktorov (Numerical methods for reactor calculation), M. Atomizdat, 1958). With $\beta = \Sigma_0 t$ and $\beta_0 = \Sigma_0 t_0$, the ratios between filter thickness t and indicator thickness t_0 and the "draw-out-length" of neutrons from the resonance region l/Σ_0 , corresponding to its maximum,

$$\begin{aligned} \eta(\beta, \beta_0) = & f(\beta_0) - f(\beta) \left(2 + \frac{\beta_0}{\beta} \right) + \\ & + \frac{\beta_0}{\beta} \left[\left(\beta + \beta_0 - \frac{\beta_0^2}{12} + \frac{\beta_0^3}{192} \right) I_0 \left(\frac{\beta}{2} \right) + \right. \\ & \left. + \left(\beta + \frac{\beta_0}{2} + \frac{\beta_0^2}{12} - \frac{\beta_0^3}{192} \right) I_1 \left(\frac{\beta}{2} \right) \right]. \end{aligned} \quad (6)$$

Card 2/4

Use of resonance indicators...

21409
S/089/61/011/006/005/014
B102/B138

is found. This relation is used for calculating the blocking factors (cf. Table 1). I_0 and I_1 are zeroth and first-order Bessel functions of an imaginary argument. Good indicators will show a broad energy gap between first and second resonance activation cross sections. Table 2 gives the characteristic parameters of several isotopes which are recommended as indicators. Only for In^{115} , Au^{197} (broad resonance) and La^{139} (narrow

resonance), the relation $\Sigma_0' = \begin{cases} \Sigma_0 & \text{for } \Gamma \ll \Gamma_0 \text{ (narrow resonance)} \\ \Sigma_0 \frac{\Gamma}{\Gamma_0} & \text{for } \Gamma \gg \Gamma_0 \text{ and } \Gamma \approx \Gamma_f \text{ (broad resonance)} \end{cases}$

holds; for the others, Σ_0' has to be determined experimentally. If the contributions of higher resonances to the neutron spectrum are negligible, the activity induced by first-resonance neutrons may be determined by the so-called "1/v law". This method is demonstrated for two isotopes, the first of which has resonance at $E = E_0$, the second one obeys the 1/v law ($\text{B}^{10}(\text{n}, \alpha)$). The neutron flux is determined from

Card 3/84

Use of resonance indicators...

21109

S/089/61/011/006/005/014
B102/B138

$$\varphi(E_0) = \frac{A_1 - A_2 \frac{\sum_{a,1}^m \zeta_1}{\sum_{a,2}^m \zeta_2}}{\frac{\pi}{2} \Gamma_Y \Sigma_0 \zeta_1} \quad (8).$$

This method was used to determine the flux distributions of the 4.9-ev resonance neutrons in the reflector of the BP-5 (BR-5) reactor. A gold foil of 1.38 mg/cm² ($\beta_0 = 0.14$) with gold filters of 3.05 and 6.10 mg/cm² ($\beta = 0.31$ and 0.62) was used. Results are shown graphically and discussed in brief. The 2.95-kev neutron flux in the Ni reflector of a BP-1 (BR-1) reactor was also measured by this method, using a Na₂CO₃ indicator foil as 1/v detector. The authors thank A. I. Leypunskiy for interest, and I. I. Bondarenko and V. V. Orlov for discussions. There are 4 figures, 2 tables, and 4 Soviet references.

TITLE:

Calculation of the characteristics of a proportional counter for dosimetry of mixed gamma-neutron radiation

SOURCE:

Moscow. Inzhenerno-fizicheskiy institut. Voprosy dozimetrii i zashchity ot izlucheniya, no. 1, 1962, 84-89.

TEXT: The main disadvantage of Herst dosimeters with proportional counters for γ -n dosimetry consists in the sub-barrier losses due to pulse discrimination. The errors caused by these losses are estimated for a spherical counter under the following assumptions: the counter walls and the filling gas have the same atomic composition; the counter dimensions are small in comparison with the mean free paths of protons and electrons in the filling gas; the radiation flux is isotropic; the specific ionization of the particles inside the counter remains constant; absorption in the walls is negligible; ionization due to recoil protons and electrons originating in the counter walls is taken into account. The proton pulse-height spectrum is calculated. It is obtained as

Card 1/3

S/892/62/000/001/013/022
B102/B186

Calculation of the characteristics...

$$dN/d\sigma = \int_{\sigma_{\min}}^{\sigma_{\max}} k(\sigma) \xi d\sigma, \text{ where } k(\sigma) d\sigma = - \frac{\pi n_0}{2q^3} \left[1 - \frac{E(\sigma)}{E_0} \right] \alpha \beta \sigma^{\beta-4} d\sigma, \quad E = \alpha \sigma^{\beta}$$

characterizes the dependence of the proton energy and the specific ionization - an approximation that causes an error not above 10% for $\beta = -1.4$ and $\log \alpha = 3.265$. $\xi = \sigma l$ is the total ionization, proportional to the pulse height; q is the density of the wall material, n_0 the total number of protons produced per cm^3 of the wall material, E_0 the neutron energy; σ_{\min} and σ_{\max} are the minimum and maximum values of specific ionization, so that σ_{\min} is the maximum energy of protons produced in the wall. If dn denotes the number of pulses with amplitude between ξ and $\xi+d\xi$, then $dn/d\xi = \xi k(\sigma) d\sigma$. If the difference in proton contribution in the two ξ ranges is taken into account,

$$\frac{dN}{d\xi} = \alpha \beta \frac{\pi n_0}{2q^3} \cdot \left[\left(\frac{\sigma_{\max}^{\beta-3}}{\beta-3} - \frac{\sigma_{\min}^{\beta-3}}{E_0 \sigma_{\max}^{\beta-3}} \right) - \left(\frac{\sigma_{\max}^{\beta-3}}{\beta-3} - \frac{\sigma_{\min}^{\beta-3}}{E_0 \sigma_{\min}^{\beta-3}} \right) \right]; \quad (9)$$

TITLE: Investigation of the uranium rod assembly of the BP-5
(BR-5) reactor

PERIODICAL: Atomnaya energiya, v. 12, no. 1, 1962, 56-57

TEXT: Some characteristics and parameters of a uranium-rod assembly exposed to a $5 \cdot 10^{21}$ neutron flux in a BR-5 reactor have been determined. The BR-5 reactor uses plutonium as fuel and uranium as reflecting material; the reflector consists of 3 cm natural uranium + 30 cm nickel. The middle of the assembly studied was 12.6 cm off the reactor center. The distributions of the absolute number of fission events in the uranium and of the capture events in U^{238} were determined for the length of the assembly (28 cm), the first from the absolute activity of Cs^{137} , and the second from the Pu-concentration in the uranium, i.e. its specific α activity. From the Pu separated from the assembly, the Pu^{240} content

Investigation of the uranium rod...

(~0.1 %) was determined by comparing the intensities of spontaneous fissions in sample and standard. Correction (~5 %) was made for the spontaneous fissions of Pu²³⁸. From the Pu²⁴⁰ content in plutonium and the Pu²³⁹ content in uranium, the mean ratio of the capture cross sections of Pu²³⁹ and U²³⁸ was calculated. With 1.81 ± 0.15 it was not far from 1.93, the value calculated by multi-group theory (18 groups). From the mean cross sections of 0.23 b (U²³⁸, capture) and 2.18 b (Pu²³⁹ fission) the mean capture cross section for Pu²³⁹ ($\sigma_c = 0.415 \pm 0.035$ b) and $\alpha = \sigma_c/\sigma_f$ can be determined ($\alpha = 0.19 \pm 0.02$). α is the ratio of the mean cross sections of radiative capture and fission. The α -values determined in dependence on energy agree with those found by V. N. Andreyev (Atomnaya energiya, 4, vyp. 2, 185 (1958)). The authors thank A. I. Leypunskiy, O. D. Kazachkovskiy and I. I. Bondarenko for their interest, and M. K. Golubeva, V. I. Moiseyev, A. S. Tishin, and Yu. M. Turchin for assistance. There are 2 figures and 4 Soviet references.

TITLE: Cosmic radiation doses

SOURCE: Akademiya nauk SSSR. Iskusstvennyye sputniki Zemli,
no.12, 1962, 35-46

TEXT: Data on primary cosmic radiation, radiation from solar outbursts and radiation belts surrounding the earth above the atmosphere, previously published in Soviet and Western scientific papers, are studied in relation to man's flight in space. These are used as a basis for a theoretical calculation of the "biological doses" within and outside a space-ship. The "biological dose" of radiation is determined by: 1) the quantity of radiation absorbed by a given tissue and 2) the relative effectiveness of the radiation depending on its nature. Conclusions are drawn as to the required thickness of a protective aluminium shell, concerning the daily dose of natural radiation absorbed by man on earth, and the safe limit of professional irradiation.

Card 1/3

S/560/62/000/012/004/014

Cosmic radiation doses

The "biological dose" of each component of the primary cosmic radiation is calculated on the basis of data on the linear density of energy loss of this radiation in NaI (Vornov, S.N., Chudakov, A.Ye. et al., Rep. Akademiya nauk SSSR, 125, 304, 1959.)
The power of the penetrating radiation of solar outbursts is calculated according to the formula:

$$P_{ion} = 1.60 \times 10^{-8} \cdot 3600 \int_{R_1}^{\infty} \Phi (R + R_1) S (R) dR (\text{rad/hour}^{-1}),$$

where P_{ion} = power of the absorption dose connected with ionization losses of protons, $\Phi (R) dR$ = proton flux with path from R to $R+dR$ ($\text{in } g \cdot \text{cm}^{-2}$), $S(R)$ = ionization loss of protons with path R , R_1 = thickness of the absorber.

Assuming an exponential function for the energetic spectrum of protons and using an approximate relation between E and R , the maximal biological doses absorbed by an organism within a space-ship are determined for different thicknesses of the protective shell. A similar formula is used for the power of the internal radiation belt

Card 2/3

S/560/62/000/012/004/014
I063/I263

Cosmic radiation doses

surrounding the earth. Here the doses are calculated also outside the space-ship where electrons and low-energy protons must be taken into account.

A protective shell of 1 g.cm.⁻² aluminium is sufficient against the electrons of the external radiation belt, but a Bremsstrahlung is produced at the walls of the ship. Its intensity in the center of a container is calculated theoretically and the results are compared with direct measurements performed by means of a scintillator in the first Soviet rocket (Vernov, S.H., Chudakov, A.Ye., U.F.N. 70, 585, 1960). A satisfactory agreement is obtained if the energies of the high-energy electrons in the external radiation belt are more than 2 MeV. There are 2 tables. TITLE: On calculating the self-absorption and self-scattering of β radiation in gas

SOURCE: Voprosy* dozimetrii i zashchity* ot izlucheniya, no. 2, 1963, 133-136

TOPIC TAGS: self-absorption, self-scattering, β radiation, gas, gas pressure

ABSTRACT: The authors derive an experimental method of accounting for self-absorption and self-scattering of β radioactive gases. Their results are plotted in a graph together with adjustment for self-absorption according to the well known formula:

$$\eta = \frac{1 - e^{-\frac{\bar{\mu}_0 H x}{(1 + \alpha t) \cdot 760}}}{\frac{\bar{\mu}_0 H x}{(1 + \alpha t) \cdot 760}} \quad (4)$$

Card 1/2

ACCESSION NR: AT4021261

where ρ_0 is the density of the gas 760 mm mercury and 0°C ; x is the linear dimensions of the measuring compartment, as well as the formula

$$\eta = e^{-\frac{\mu \rho_0 H x}{(1 + \alpha t) \cdot 760}}$$

(5)

The theoretical calculation and the adjustment according to the above formulas can lead to an error of 20%. In each specific case, the authors obtain an empirical formula for introducing the adjustment of self-absorption and self-scattering by means of a graph. Orig. art. has: 9 formulas and 2 figures.

Collection of problems on dosimetry¹⁹ and protection from ionized radiation (Sbornik zadach po dozimetrii i zashchite ot ioniziruyushchikh izlucheniye) Moscow, Atomizdat, 1964. 134 p. illus., biblio. 4500 copies printed.

TOPIC TAGS: radiation dosimetry, ionizing radiation, nuclear radiation, radiation protection, radioisotope, radiation hazard

PURPOSE AND COVERAGE: This collection of problems is intended for students and others concerned with radioisotopes, dosimetry, and protection against nuclear radiation. The textbook contains about 400 fundamental problems and their answers on dosimetry and radiation protection, together with the fundamental formulas and relationships needed for the solution of these problems. Some complex auxiliary problems are also included. Course materials, used over a period of years in the Moscow Physics and Engineering In-

TITLE: High-frequency transformer sensor for small linear movements

SOURCE: Izmeritel'naya tekhnika, no. 5, 1964, 6-8

TOPIC TAGS: sensor, measurement sensor, hf transformer sensor, accelerometer, vibrometer

ABSTRACT: The design, functioning, and characteristics of a differential h-f sensor suitable for vibrometers and accelerometers are considered. Only a tuned type has a sensitivity high enough (60 mv/micron) to warrant changing from the conventional l-f to a h-f design. This sensitivity, enabling one to measure fractions-of-a-micron movements, and the absence of a magnetic circuit, which simplifies zero-drift compensation, are regarded as advantages of the h-f sensor. An extreme sensitivity to the supply-voltage frequency (about 100 kc) is regarded

Card 1/2

ACCESSION NR: AP4041340

as a disadvantage; the frequency error of the sensor can be brought under 0.2% if a quartz-stabilized h-f oscillator is used. However, even without the quartz stabilization, the sensor's zero signal was within 0.5—2 mv, according to the experimental data reported. Orig. art. has: 4 figures and 13 formulas.

TITLE: Increases in the hard component of cosmic ray intensity during "small" solar chromospheric flares

SOURCE: Geomagnetizm i aeronomiya, v. 4, no. 2, 1964, 399-401

TOPIC TAGS: hard cosmic-ray component, cosmic ray, solar flare, solar chromosphere

ABSTRACT: An analysis is made of 170 flares of two units of intensity or more as reported by a world network of stations registering the hard component of cosmic ray intensity during small chromospheric flares. The method of period superposition is used, and the daily variation is eliminated by subtracting the daily variation from the preceding day. The results, summarized in a table, show that the magnitude of the effect is not larger than 0.1%, or less than reported earlier by the same group of authors. Statistical processing indicates that roughly 75% of the effect at the equator is due to secondary effects which are most probably of high atmospheric origin. The authors thank M. Murzabekov for the help during the processing of the results and

AUTHOR: Ivanov, V. I.

TITLE: X ray and thermogravimetric study of the octahydrate sul-
fates of the lanthanoids and yttrium B

SOURCE: ²¹ Kristallografiya, v. 9, no. 5, 1964, 655-659 ²⁷

TOPIC TAGS: yttrium, lanthanoid group, x ray structure, crystal
lattice structure, crystal lattice constant, hydrate, sulfate

ABSTRACT: A systematic study was made, as part of structure inves-
tigations, of the lanthanoid compression in the series of octahy-
drates of the sulfates of lanthanoids. The study was based on an
exact measurement of the periods a and c of the cells, and also the
monoclinic angles β , using a diffractometer. The parameters b were
determined from rotation x-ray pictures obtained during the course
of the exact adjustment of the crystals prior to installation in

Card 1/5

L 7013-65

ACCESSION NR: AP4046043

the diffractometer. Sulfates of the compounds from Pr to Lu, including Y, were measured, and comparison with a quartz crystallite of the same dimensions has shown the accuracy to be within 0.02%. The results of the measurements of the parameters are listed in Table 1 of the enclosure. The unit-cell parameters are shown in Fig. 1 of the enclosure as functions of the atomic number. The variation of the cell parameters was found to be monotonic without any kinks near Gd. A thermogravimetric study of the compounds of Eu, Er, and Yb was made to determine the character of the bond of the water in the octahydrates of the lanthanoid sulfates, using equipment described by P. N. Paley et al. (Zh. analit. khimii v. 12, 318, 1957) and I. S. Sklyarenko et al. (Zh. analit. khimii, v. 15, 706, 1960). The results show that the water is removed from all the investigated octahydrates in the temperature interval 100--250C without formation of any intermediate hydrates. It is concluded from these tests, and also from x-ray powder patterns corresponding to different stages of the dehydration process, that the water mole-

Card 2/5

L 7013-65

2

cules are rather weakly bound and their removal does not destroy the skeleton of the structure. Moreover, anhydrous sulfates tend to absorb water and restore the initial structure of the octahydrate. "The author is deeply grateful to Ye. S. Makarov for continuous interest in the work." Orig. art. has: 4 figures and 2 tables.

Dosimetry of ionizing radiation (Dozimetriya ioniziruyushchikh izlucheniye) Moscow, Atonizdat, 1964. 263 p. illus., biblio. 6000 copies printed. Editor: A. A. Muradova; Technical editor: G. L. Usachev; Proofreader: N. A. Smirnova

TOPIC TAGS: x radiation, charged particle, radioactive aerosol, gamma radiation, electromagnetic radiation, nuclear radiation, radiation dosimetry, radiometry, gamma radiation, neutron radiation, ionizing radiation, nuclear engineering

PURPOSE AND COVERAGE: This book has been authorized by the Ministry of Higher and Secondary Special Education of the RSFSR as a text for students in engineering-physics and physical-technical higher educational institutions and faculties. The book will be useful also to engineers, technicians, and laboratory personnel occupied with practical problems of measuring the dosage of nuclear radiation. The text is based on the lecture course presented by the author at the Moscow Engineering-Physics Institute and is directed toward the reader who is already acquainted with atomic and nuclear physics and with methods of recording radiation and the interaction of radiation and materials. Soviet scientists who have contributed significantly to the field of radiation dosimetry are K. K. Aglintsev, N. G. Gusev, B. M. Isayev, O. I. Leypunskiy, and I. B. Keirim-Markus.

TITLE: Distribution of the ratio of the radiative-capture and fission cross sections for Pu-239 over the height of the BR-5 reactor

SOURCE: Atomnaya energiya, v. 16, no. 6, 1964, 497-500

TOPIC TAGS: neutron capture, capture cross section, fission cross section, breeder reactor, neutron flux neutron spectrum

ABSTRACT: This research was undertaken because of the interest that attaches to a knowledge of the cross-section ratio for the determination of the breeding ratio, for the choice and averaging of the microscopic constants, and for reactor design in general. The distribution of the neutron-capture reactions was measured by determining the Pu²⁴⁰ concentration from the rate of spontaneous fis-

Card 1/5

ACCESSION NR: AP4041447

sion in plutonium samples irradiated in a reactor with integral flux 10^{21} -- 10^{22} neut/cm². The initial material for the irradiation was Pu²³⁹ of almost isotopic purity (containing $\approx 5 \times 10^{-3}\%$ Pu²⁴⁰). The distribution of the Pu²³⁹ fission in the reactor was measured by two methods -- with the aid of a fission chamber and by determining the activity of the fission products from the irradiated samples. The Pu²³⁹ capture cross section could be determined from the Pu²⁴⁰ concentration and the integral neutron flux. The values obtained for the ratio of the radiative capture to fission cross section (α) increase from 0.1 to 0.8 with increasing distance from the reactor center. Data corresponding to the equilibrium spectra of the neutrons in the active zone and in the outer region of the reflector agree with the measured capture and fission cross sections for monoenergetic neutrons. When group calculation is used, the values agree with the calculated ones only for the active zone, with noticeable discrepancies in the reflector. "This work was performed under the general guidance of I. I. Bondarenko and A. P.

TITLE: Device for contactless measurement of rotor sag. Class 42, No. 176106
/announced by Moscow Order of Lenin Aviation Institute, im. Sergo Ordzhonikidze
(Moskovskiy ordena Lenina aviatsionnyy institut) 44

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 21, 1965, 61

TOPIC TAGS: electronic circuit, detection equipment

ABSTRACT: "This Author Certificate presents a device for contactless measurement of rotor sag. The device contains a capacitive unary sensor included in a resonance circuit supplied by a high frequency oscillator, a detector, and a matching stage with a meter (see Fig. 1). To simplify the measuring process and to increase the readout accuracy, a compensating capacitor is inserted in the resonance circuit in series with the sensor. The capacitor insures a linear dependence between the magnitudes of the output voltage and rotor sag."

TITLE: Effects of small bursts in the hard component of cosmic rays on quiet and magnetically disturbed days

SOURCE: Geomagnetizm i aeronomiya, v. 5, no. 4, 1965, 673-678

TOPIC TAGS: cosmic ray shower, diurnal variation

ABSTRACT: This paper presents an analysis of cosmic ray bursts occurring on magnetically quiet and disturbed days. The bursts are classified into three groups. Statistical accuracy was increased by double averaging: by stations and for all bursts. Solar-diurnal variations were excluded. Data for 19 stations (210 bursts) were used (120 observations on magnetically quiet days and the others at the time of Forbush decreases. Orig. art. has: 4 figures and 1 table. [JPRS]
